Part-E → Explain it-
E-1 → Sudheer Kumar_A4_E.txt

① → Why do we make an attribute with two underscores instead of leaving it Public?
→ Prevent attributes be changed → Any one using your code can see, change, or break/alter them from the outside.
→ prevent Name clashes → If Parent class has a variable named __marks and a child also creates a variable named __marks, they will not overwrite each other. Python automatically change them adding Parentclass name and child class name.
→ Safety from mistakes → It mentions/signals that the variable belongs strictly to that specific class and prevents accidental changes during Inheritance.

② → Why is a CSV file often more useful than a plain text file for this kind of data?
→ CSV file organizes information into structured row and columns that make it instantly readable as a table by spreadsheet and other database S/W.
→ CSV file is human and machine friendly oriented. That is read using a basic text editor.

③ → Why does Json file give you that CSV does not?
→ Json file gives us nested data structures and real data types, which CSV does not provide us.
→ Json file knows and tells the difference between text, numbers, true/false and empty values.
But CSV does not tells that all. CSV tells us everything as plain text format.

④ → Why put anything in a finally block at all, when the code after the try would run anyway?

→ try block does not give guarantee to run the code.
But finally block gives guarantee to run the code.
